# Experimental aspects of heavy quarkonium production at the LHC

Aafke Kraan  
INFN Pisa

**Three Days of Strong Interactions and Astrophysics HLPW 2008**  
*Joint Meeting Heidelberg-Liège-Paris-Wroclaw*

# Outline

---

- **Introduction**
- **Quarkonium production in PYTHIA 6.409**
- **J/psi production studies**
- **Upsilon production studies**
- **Quarkonia measurements planned at LHC**
- **Plans and conclusions**

# Motivations

The J/psi has been discovered more than **30 years** ago... and has since then been studied by many experiments like Tevatron, HERA, ...

$$Q\bar{Q} = c\bar{c}, b\bar{b}$$

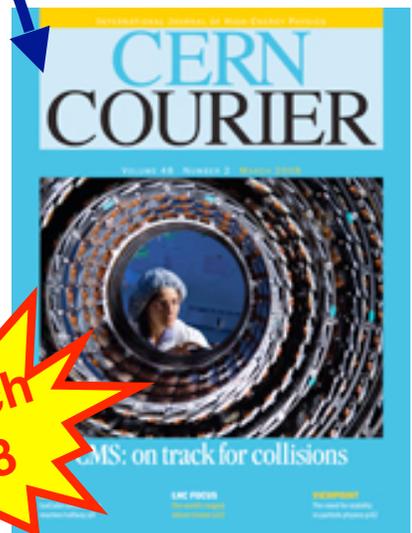

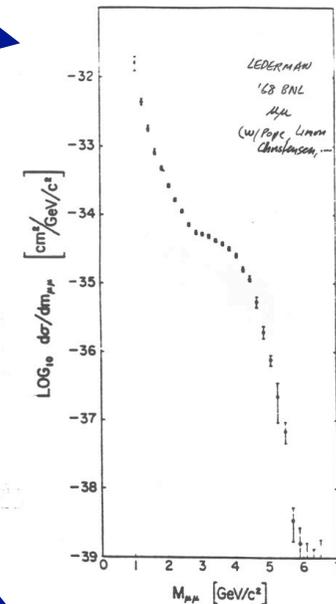

## Why still study quarkonia at the LHC?

- Still today quarkonium production not understood!
  - Experimental data not understood!
- Theoretically recently lots of progress made, calculations should be compared with LHC data
- The LHC allows for new studies: higher  $P_T$  & luminosity!
- Quarkonia crucial to understand detectors (alignment, calibration)

Still lots of interest for quarkonia studies at LHC!

Spa, 6-8 March 2008

IN THE BEGINNING, .....

March 2008

# Quarkonium production models

Before CDF Run 1: J/psi's thought to be produced via **singlet mechanism**.  
 CDF data factor 50 above theory

➔ **New approaches developed!**

➤ **Non-Relativistic QCD-formalism**

● Quarkonium state written as expansion in  $v$  in Fock-space:

( $v$  = velocity of Q in bound state in CM) ➔ **singlet&octet mechanism**

● Octet contribution could explain  $P_T$  spectrum at Tevatron, but not polarization!

➤ **NNLO singlet** calculations

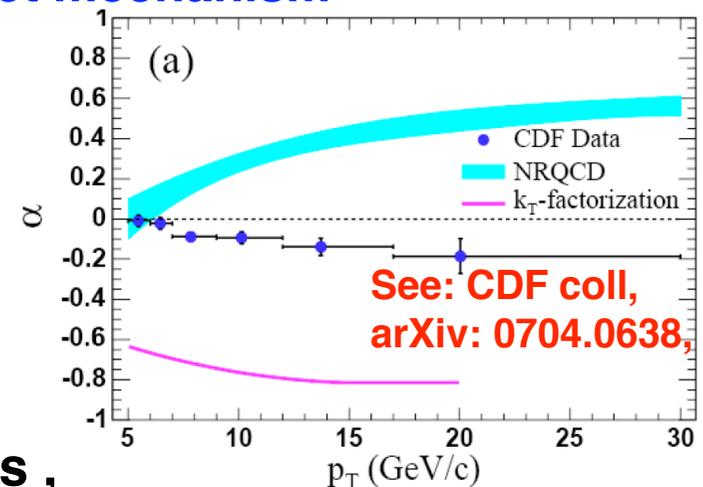

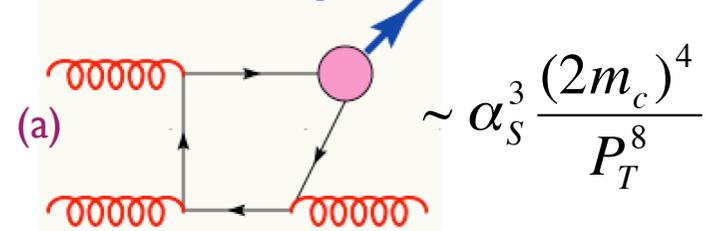

➔ no need for octet??

➤  **$K_T$  factorization** approach

➤ Older models: soft-colour-Interaction models, colour-evap. models, ..

main LO singlet contribution

Overview see J.-P.Lansberg, Int.J.Mod.Phys.A21:3857-3916,2006

# Quarkonium production at LHC

There are several ways to study (prompt) quarkonium production

➤ **Diff. cross section** measurements → **Will be done in first months**

Important, but cross section sensitive to many factors (slide 10+24)...

➤ **Polarization** measurements → **Will be done in first months**

Gives important information on production mechanism

➤ **Hadronic activity** around  $J/\psi$  → **Possible? Not yet clear!**

Might give complementary information on production mechanism (idea with **Torbjörn Sjöstrand**) → today

**How?** Compare models with different shower activity and try to investigate sensitivity of typical LHC detector (ATLAS or CMS).

**These three measurements together should allow the quarkonium production puzzle to get solved at LHC!**

**NB1: For quarkonium measurement, so far concentrate on muon decays!  $BR(J/\psi \rightarrow \mu\mu) = 5.98\%$   $BR(Y \rightarrow \mu\mu) = 2.48\%$**

**NB2: Prompt production! But do not distinguish between direct&indirect.**

# Outline

---

- Introduction
- **Quarkonium production in PYTHIA 6.409**
- J/psi production studies
- Upsilon production studies
- Quarkonia with first very LHC data!
- Plans and conclusions

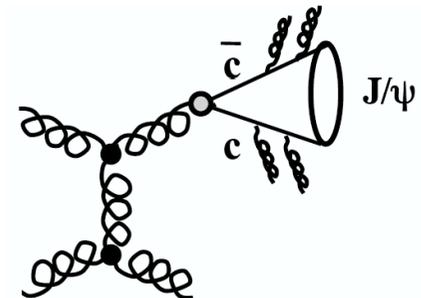

# Quarkonium event generation: Pythia 6.409

**Original implementation** by S. Wolf (2002, never in official release)

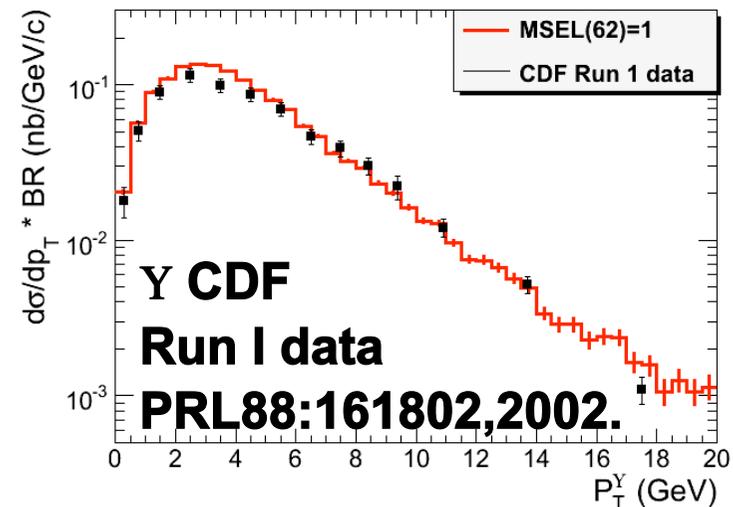

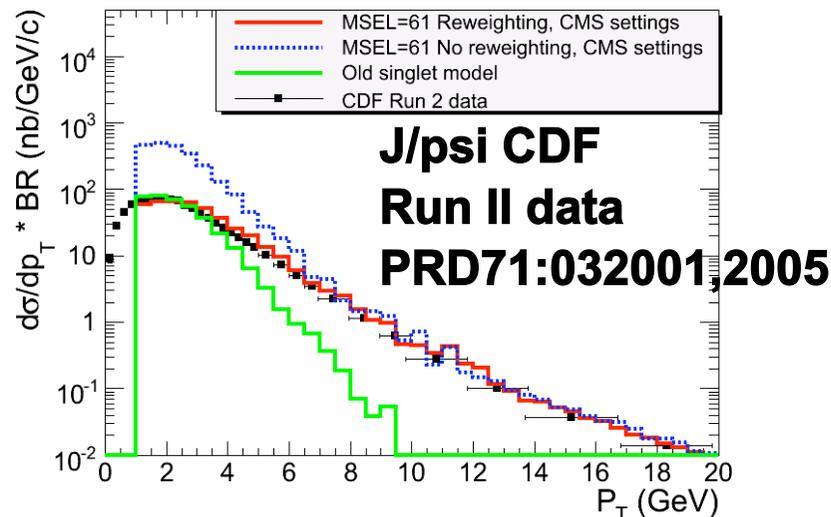

- Based on NRQCD- approach
- Singlet and octet  $Q\bar{Q}$  produced perturbatively, followed by shower
- Parton showers for radiation off octet  $Q\bar{Q}$ : switches: MSTP(148),MSTP(149)

**Recent (2006,2007) progress:**

- Code integrated (Sjöstrand): PYTHIA  $\geq 6.324$
- Possibility to dampen cross section at small  $P_T$  like for  $gg \rightarrow gg$  in underlying event (PYEVWT)
- NRQCD matrix elements tuned [See Bargiotti, CERN-LHCb-2007-042.

**For our generation:** parameters checked by generating CDF events

# We will compare 4 strawman models

➤ MC truth + LHC-like detector (CMS, ATLAS) with fast simulation

**Singlet production**

hard g

perturbative | non-perturbative

➔

- Quarkonium produced direct or via  $\chi$
- QQ-state produced in colour singlet in hard interaction
- Color singlet  $\rightarrow$  no g-radiation
- **J/psi produced in isolation!**

**MODEL 1: NO RADIATION**

**Octet production**

harder g's | soft g's

perturbative | non-perturbative

➔

- Quarkonium produced direct or via  $\chi$
- Physics-wise: shower expected from
  - 1)  $gg \rightarrow ggg \rightarrow gggg \dots$
  - 2)  $g \rightarrow QQ^{(8)}$
  - 3)  $QQ^{(8)} \rightarrow J/\psi \text{ or } Y$
- Technically: cc-octetin hard interaction
- Switches MSTP(148), MSTP(149)
- **J/psi produced in shower!**

**MODEL 2: LOW RADIATION**  
**MODEL 3: MEDIUM RADIATION**  
**MODEL 4: HIGH RADIATION**

➤ NB Model (1+2), (1+3), (1+4) all fit CDF data!

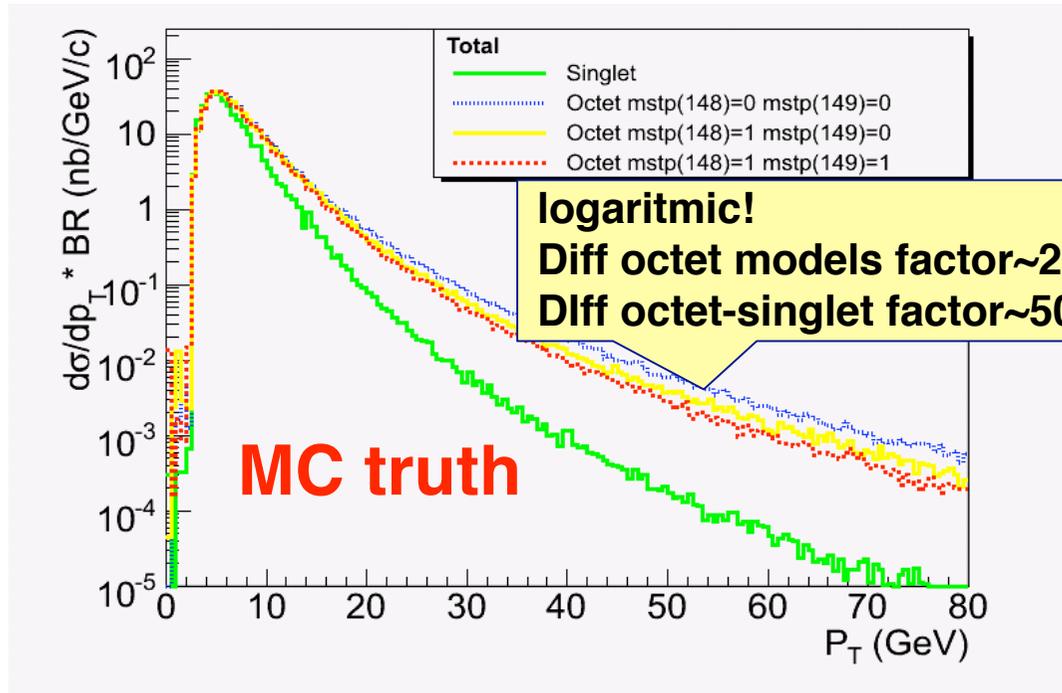

# Outline

# Prompt J/psi differential cross section

## Prompt J/psi production cross section at LHC

● In 100 pb<sup>-1</sup> (Pythia prompt J/psi singlet+octet):  $|\eta(\mu)| < 2.5$   $P_T(\mu) > 2.5$

$P_T(J/\psi) >$	Produced	Reconstructed
5 GeV	$\sim 2 \cdot 10^7$	$O(10^6)$
20 GeV	$\sim 3 \cdot 10^5$	$O(10^5)$
50 GeV	$\sim 5 \cdot 10^3$	$O(10^3)$

The cross section is excellent observable for understanding J/psi production!!

However many parameters influence cross section shape...

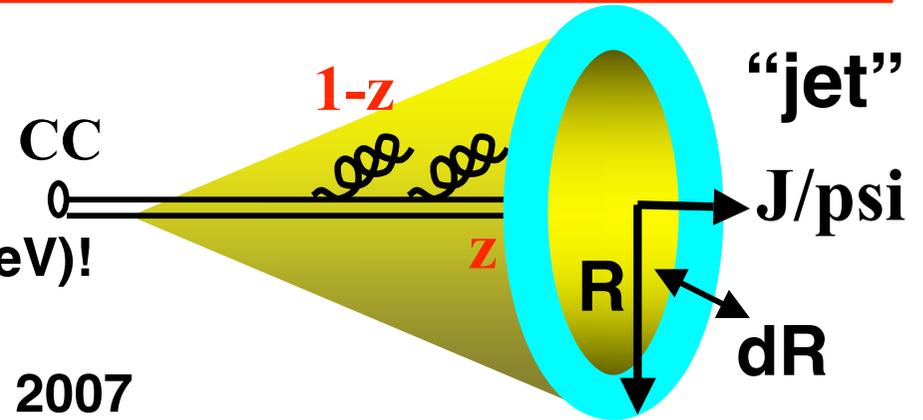

- ISR & FSR
- Mass of cc-octet
- Cross section dampening at small  $P_T$ : free parameters!

➔ Need more observables!!

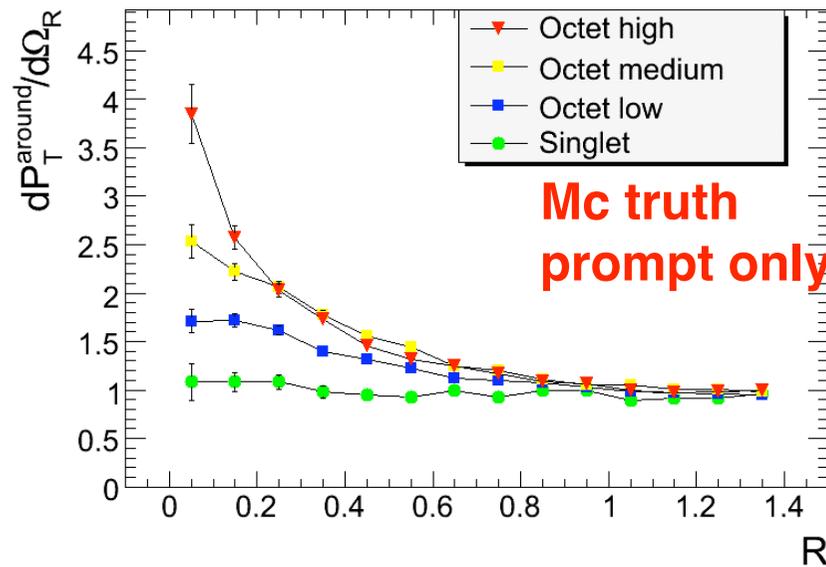

# Prompt J/psi: associated hadronic activity

- Shower activity of 4 models is different ➔ investigate activity around J/psi in cone R
- Differences at higher  $P_T(\text{jpsi}) > 20 \text{ GeV}$ !  
[low  $P_T$ : little shower]
- More info: see Quark.WG Hamburg 2007
- Example: “Pt-density” around J/psi

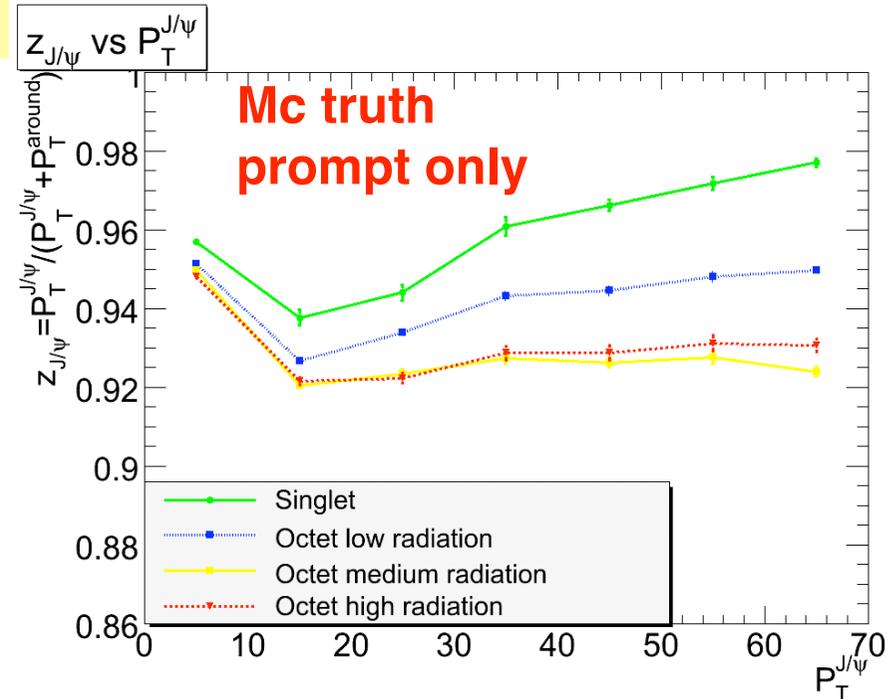

$$\frac{dP_T^{\text{around}}(R)}{d\Omega_R} = \frac{P_T^{\text{around}}(R + dR/2) - P_T^{\text{around}}(R - dR/2)}{\pi[(R + dR/2)^2 - (R - dR/2)^2]}$$

J/psi activity:  $20 \text{ GeV} < P_T^{J/\psi} < 40 \text{ GeV}$

➤ Or fragmentation var. z:

# Prompt J/psi trigger & reconstruction

**Triggers at LHC:** at low luminosity  $10^{32} \text{ cm}^2 \text{ s}^{-1}$ : typically a double muon trigger (with some threshold, e.g.  $P_T > 3 \text{ GeV}$  in CMS)

**Offline reconstruction:** Use tracker & muon chambers.

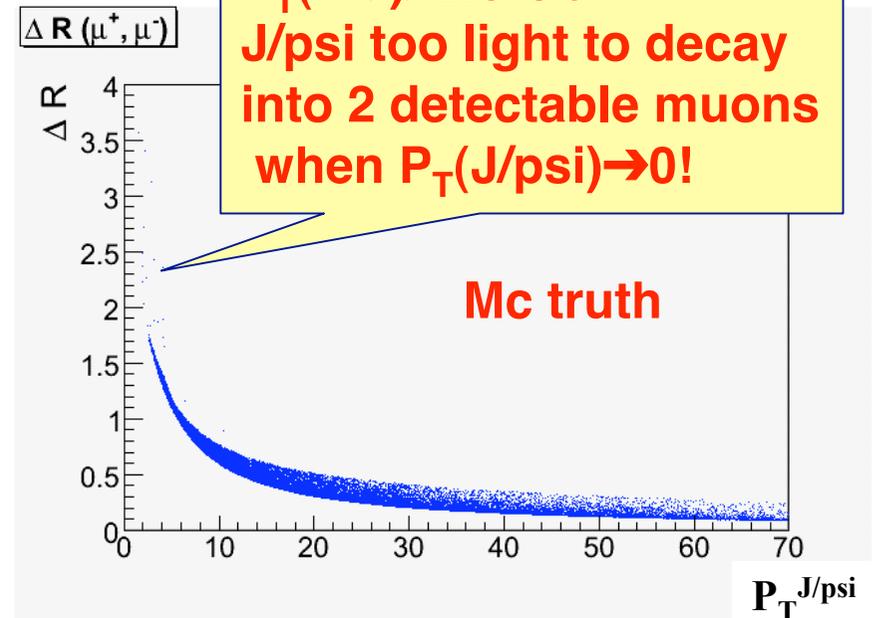

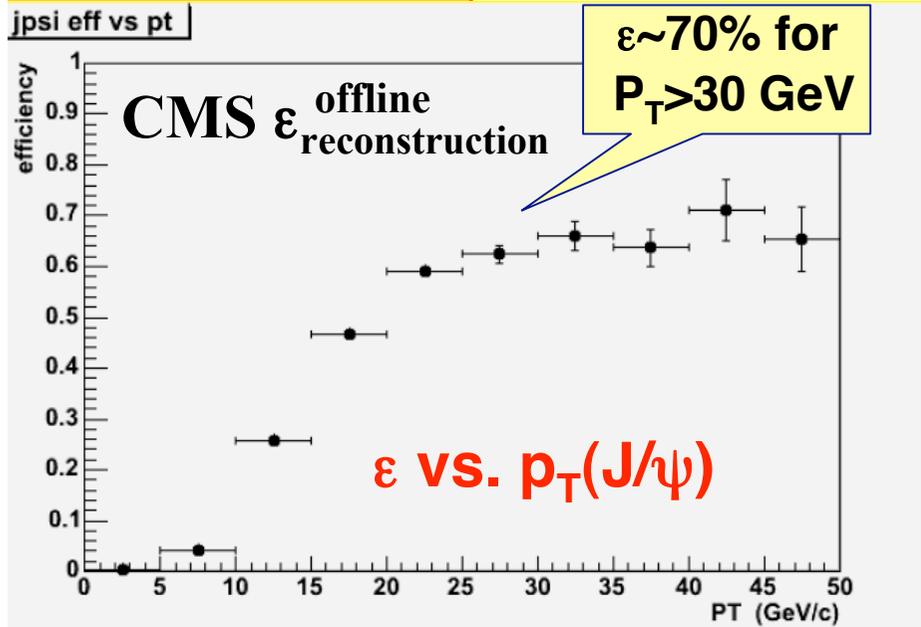

NB efficiency drops to 0 at  $P_T(\text{J}/\psi) \rightarrow 0$

NB efficiency independent of hadronic activity

Z. Yang and S. Qian,  
CMS-note 2006/094  
CMS-note-2007/017

$$\epsilon_{\text{reconstruction}} = \frac{N_{\text{reconstructed}}}{N_{\text{generated}}}$$

**Generator level filter:**  
 $P_T(\mu) > 2.5 \text{ GeV}$   
J/psi too light to decay  
into 2 detectable muons  
when  $P_T(\text{J}/\psi) \rightarrow 0$ !

Spa, 6-8 March 2008

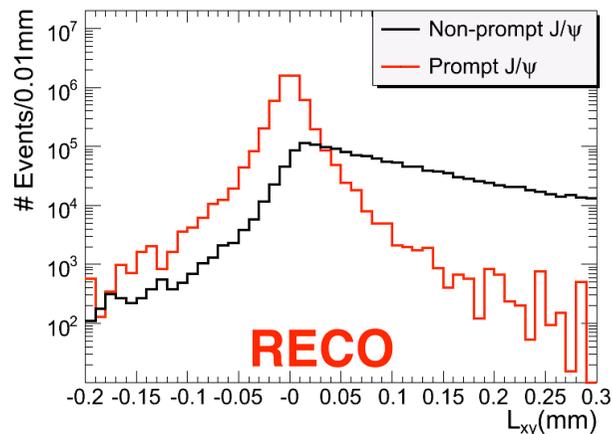

# Prompt J/psi measurements: challenges

**Background:** is important for any measurement of prompt J/psi's!

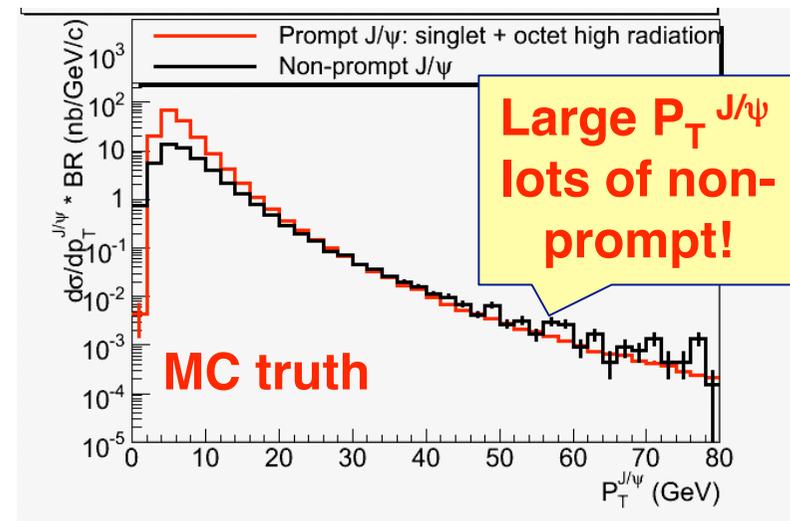

➤ **Non-prompt J/psi's ( $b \rightarrow J/\psi X$ )**

Well-known behaviour of impact parameter ➔ Evaluate amount of prompt and non-prompt background

Prompt J/psi production cross section at LHC

➤ **General QCD processes ( $pp \rightarrow \text{Mu}X$ )**

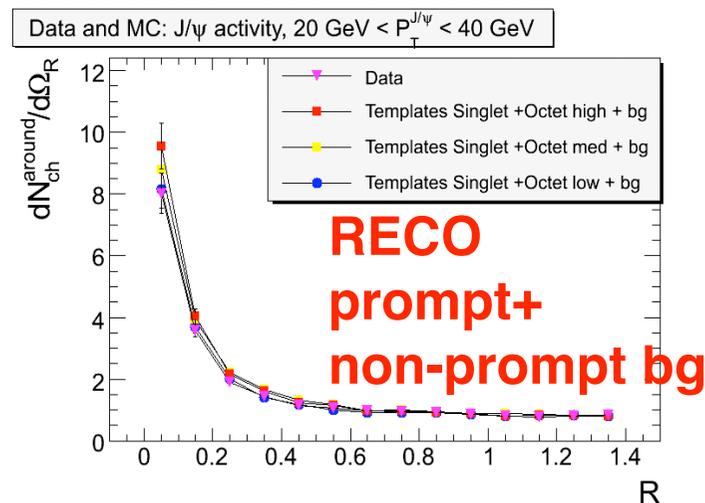

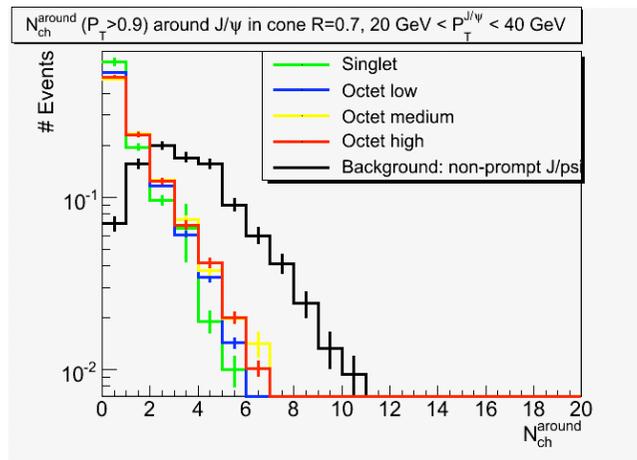

Lots of it... amount reconstructed “fake” J/psi's with mass [3.0-3.2] ~ amount prompt J/psi's. But well-known behaviour of invariant mass: subtract backgr. with techniques such as side-band-subtraction

**NB:** it's not trivial to collect background (and signal) MC statistics...

# Hadronic activity study: challenges

Unlike for cross section measurement, backgrounds is harder to deal with when studying hadronic activity!

**Background** studied so far: **Non-prompt J/psi**

**Several challenges** (making it probably not an analysis to do with first data):

- Non-prompt  $J/\psi$ 's have large amount of activity [high  $P_T$  many of them]!
- Wrong estimation of background could lead to totally wrong conclusion
- Improvements possible! (even sharper cuts on lifetime, MC statistics, separation prompt-non-prompt, use more variables together), but maybe easier for  $Y$ 's? (**no non-prompt  $Y$ 's!**)

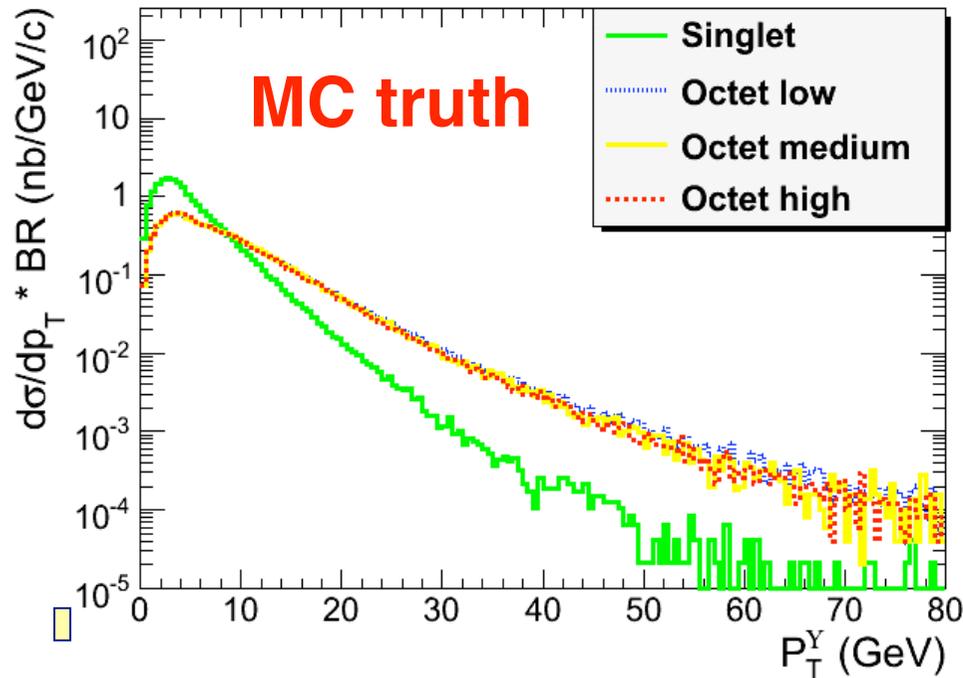

# Outline

---

- Introduction
- Quarkonium production in PYTHIA 6.409
- J/psi production studies
- **Upsilon production studies**
- Quarkonia with first very LHC data!
- Plans and conclusions

# Upsilon (1S) differential cross section

## Prompt Upsilon (1S) production cross section at LHC

● In 100 pb<sup>-1</sup> (Pythia singlet+octet):  
 $|\eta(\mu)| < 2.5$   $P_T(\mu) > 2.5$  GeV

$P_T$ (Y) >	Produced	Reconstructed
5 GeV	$\sim 6 \cdot 10^5$	$O(10^5)$
20 GeV	$\sim 2 \cdot 10^4$	$O(10^4)$
50 GeV	$\sim 5 \cdot 10^2$	$O(10^2)$

Same 4 models as J/psi generated (sl 8), and same generator cuts:

$|\eta(\mu)| < 2.5$   $P_T(\mu) > 2.5$  GeV

Compare Upsilon/Jpsi:

- Smaller cross section so 100 pb<sup>-1</sup> easy to generate
- Upsilon cross section falling less rapidly
- Differences in radiation less pronounced: the heavier the colored object, the less it radiates!

# Upsilon trigger & offline reconstruction

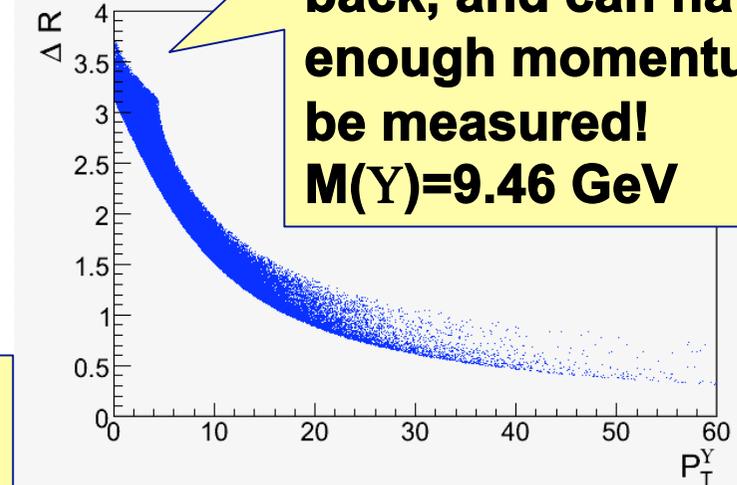

**Upsilon trigger:** as J/psi ( $2\text{Mu } P_T > 3$ ),

but with different mass window cut

**Offline reconstruction:** can do measurements down to zero!

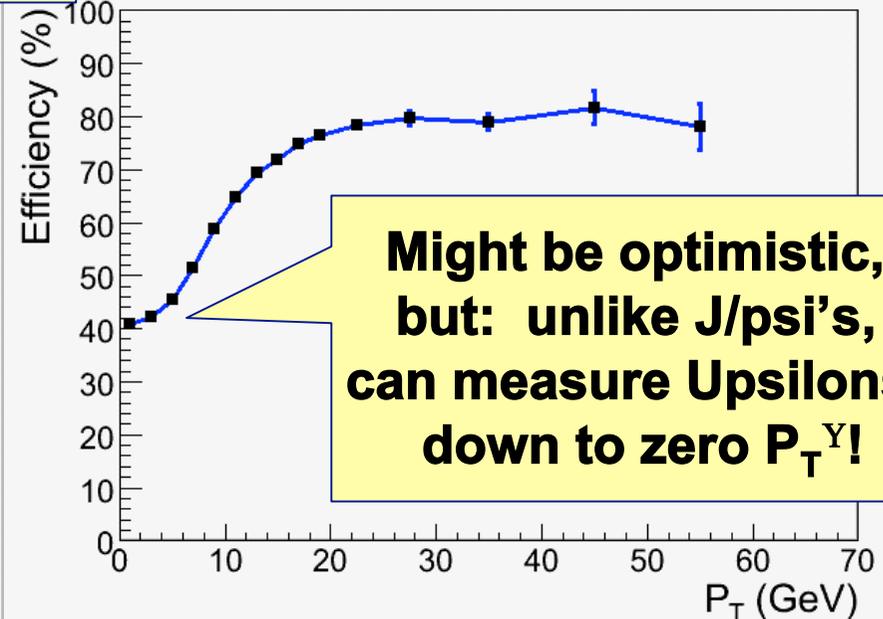

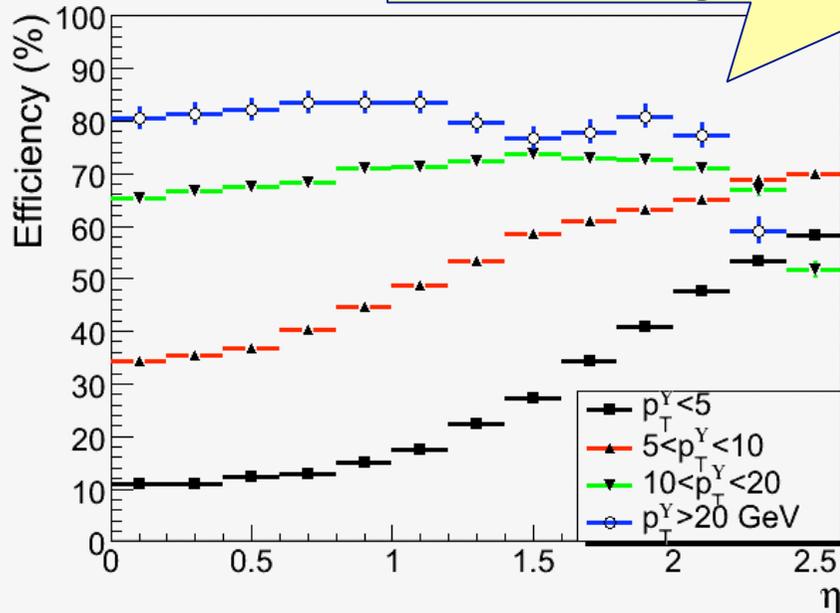

(nice for studying low  $P_T$  dampening)

$\Delta R(\mu^+, \mu^-)$

Low  $P_T^Y \rightarrow \mu$ 's back-to-back, and can have enough momentum to be measured!  
 $M(Y) = 9.46 \text{ GeV}$

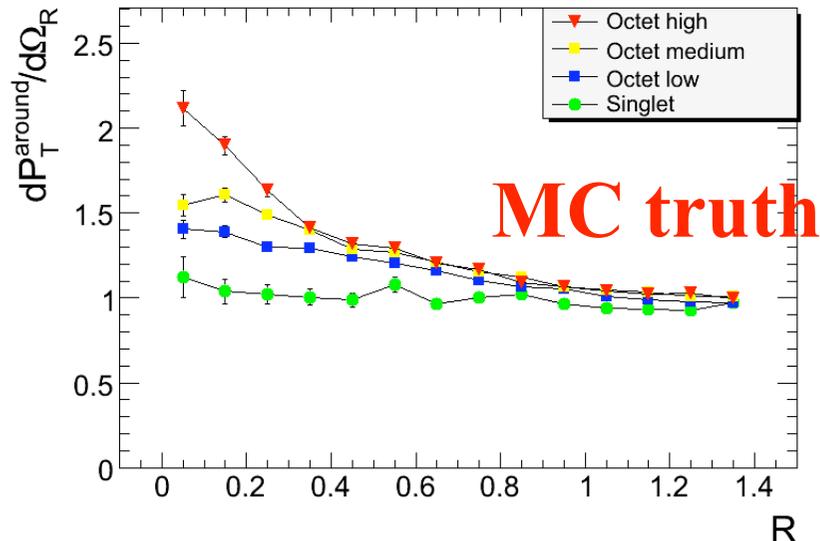

High  $P_T$ : eff decreases at large eta! muons go in eta-region  $> 2.4$

Might be optimistic, but: unlike J/psi's, can measure Upsilon's down to zero  $P_T^Y$ !

# Upsilon hadronic activity

Upsilon activity:  $20 \text{ GeV} < P_T^Y < 40 \text{ GeV}$

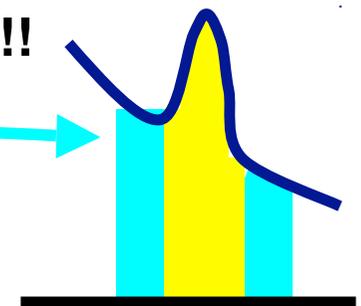

amount of radiation smaller than for J/psi

## Compared with J/psi:

- ++ Background: **no non-prompt Y's**, only QCD processes ( $pp \rightarrow \text{MuX}$ )
- - - **Amount of radiation** off bb-state is **smaller** than for cc-state.
- As J/psi, for background the activity around misidentified Y's is high (e.g. events with  $b \rightarrow \mu + b \rightarrow \mu$ )
- Not talked about: sensitive to underlying event and pile-up!!
- Current limitation: background statistics...
- **Real data:** measuring activity in sidebands of Y inv. mass should allow for a proper subtraction of the background!

# Outline

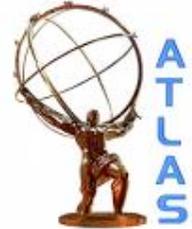

---

- Introduction
- Quarkonium production in PYTHIA 6.409
- J/psi production studies
- Upsilon production studies
- **Quarkonia measurements at LHC**
- Plans and conclusions

# Quarkonium measurements at LHC

---

## CMS & ATLAS & LHCb are planning :

- Differential cross section measurement:  $J/\psi$ ,  $\psi(2S)$ ,  $Y(1S)$ ,  $(2S)$ ...
- Polarization measurements
- Hadronization measurement (ATLAS, CMS?)
- Measurements of  $\chi_b$  and  $\chi_c$
- LHCb in addition investigating  $\psi(3770) \rightarrow DD$ .

NB All experiments focus on **muon decay** channels

More details in discussion session!

# Conclusions

---

- **Recent theory progress makes it even more exciting to compare real LHC data with theory predictions!**
- **For quarkonium studies at LHC: PYTHIA commonly used [easy in use]**
- **Cross section & polarization measurement are first observables to understand underlying quarkonium production mechanism.**
- **However, cross section is sensitive to several factors ➡ would be good with more observables!**
- **Examples of observables shown, taking into account dynamics of particles around the J/psi.**
- **Based on 4 “strawman” models in PYTHIA, clear separations visible, at larger values of  $P_T(\text{J/psi})$  ( $>30$  GeV)**
- **J/psi: non-prompt background forms problem**
- **Upsilon: less radiation, but less background: work in progress...**
- **CMS, ATLAS, LHCb are all planning quarkonium measurements based on muon decay channels**

# Thanks!

---

- **Thanks to: Torbjörn Sjöstrand, Zongchang Yang, Fabrizio Palla, Urs Langenegger, Carlos Lourenco for help & discussions, and thanks to Jean-Philippe and the organization of this conference!**

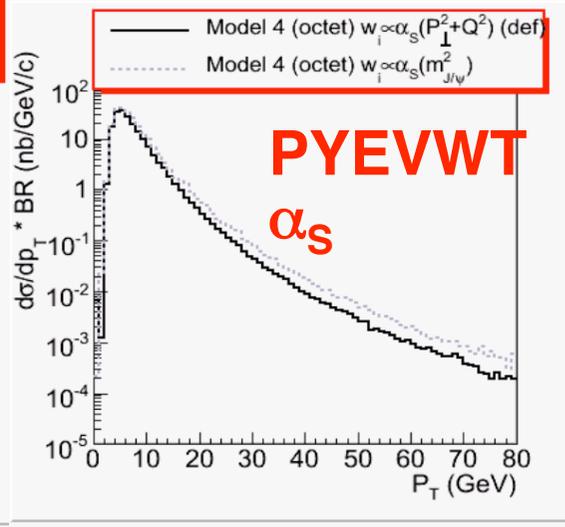

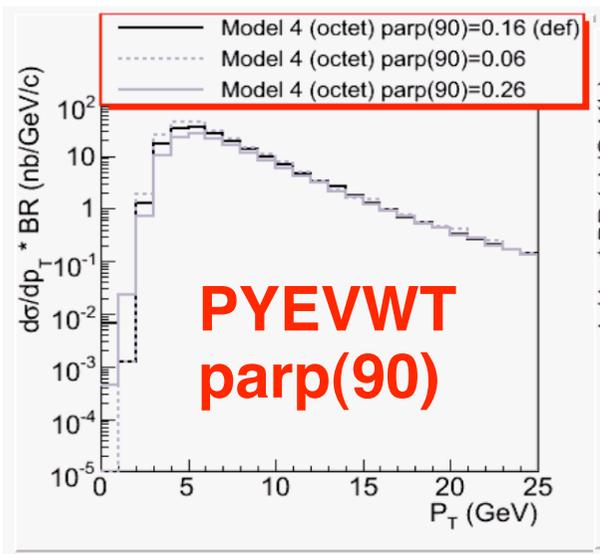

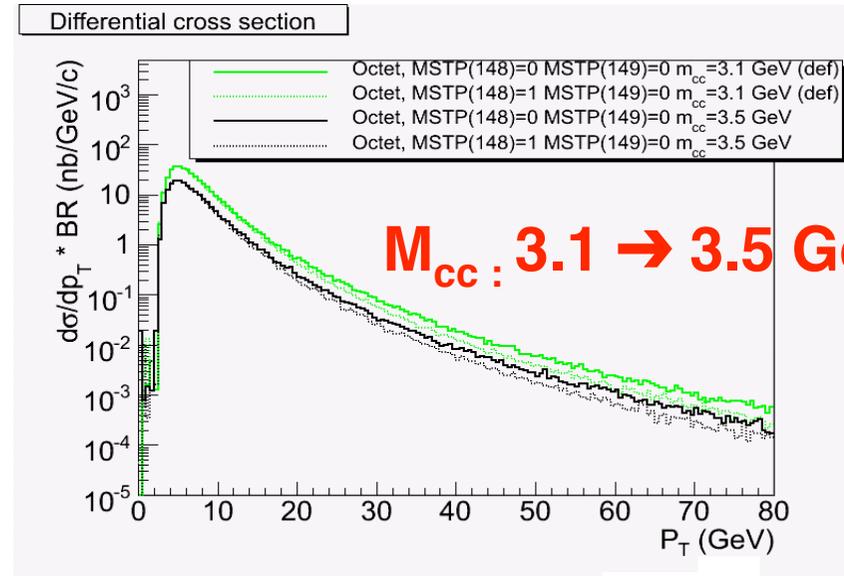

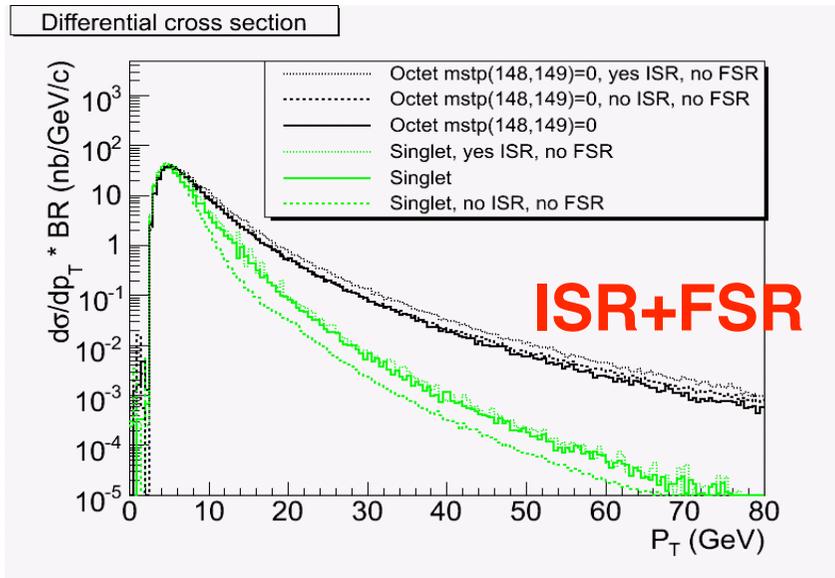

---

# EXTRA SLIDES

# Prompt J/psi differential cross section

## Examples of changes in the differential cross section:

## Conclusion:

- Diff. xs can change significantly!
- Even if we can measure the spectrum, doesn't mean we understand the production...

# J/psi production in PYTHIA: PYEVWT.f

- **Problem:** even with octet, quarkonium cross section not right shape (too big at low Pt)
- **Solution:** PYEVWT.f: cross section dampened, like  $gg \rightarrow gg$  in underlying event formalism

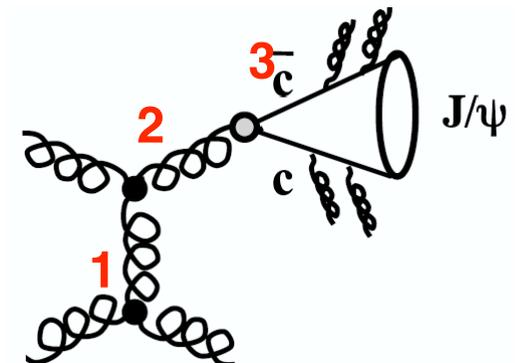

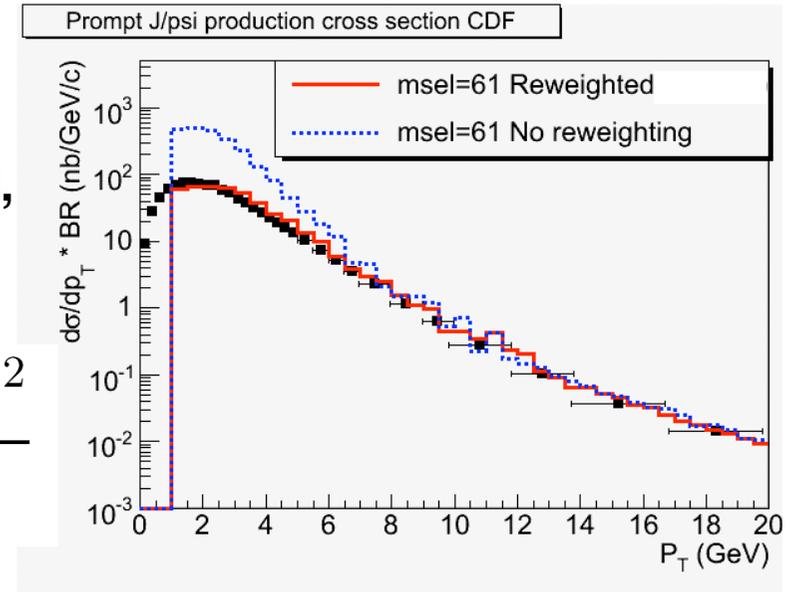

T. Sjöstrand and M.v.Z, PRD 1987

$$\frac{d\sigma}{dp_T^2} \propto \frac{[\alpha_S(p_T^2)]^2}{p_T^4} \implies \frac{[\alpha_S(p_{T_0}^2 + p_T^2)]^2}{(p_{T_0}^2 + p_T^2)^2}$$

- **Applies naturally here too!**

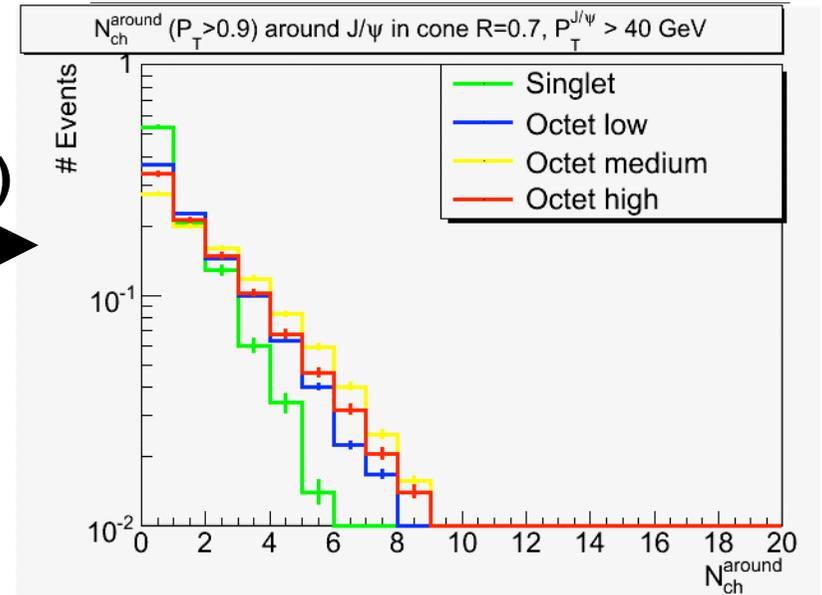

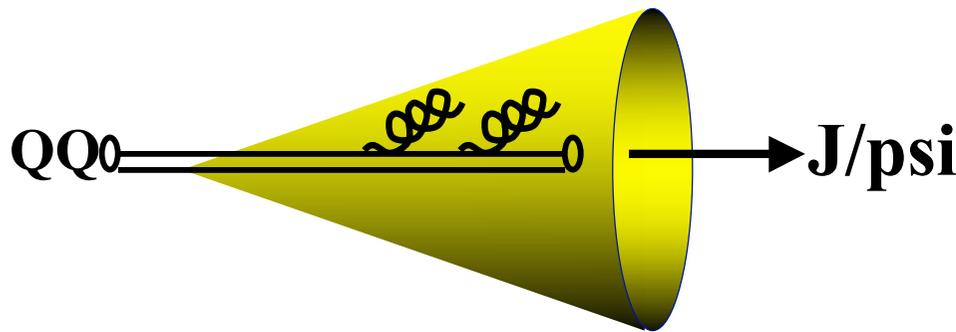

$$w_i = \frac{\sigma_{reweighted}}{\sigma_{not\ reweighted}} = \left( \frac{\hat{p}_T^2}{p_{T_0}^2 + \hat{p}_T^2} \right)^2 \left( \frac{\alpha_S(p_{T_0}^2 + Q^2)}{\alpha_S(Q^2)} \right)^3$$

- $p_{T_0} \sim$  scale below which g cannot resolve colours  $\Rightarrow$  coupling decreases  $\Rightarrow$  xs decreases!
- $p_{T_0} \sim 2$  GeV at CDF, is assumed to grow with  $\sqrt{s}$   
[x smaller  $\rightarrow$  denser packing of gluons  $\rightarrow$  more screening  
LHC:  $p_{T_0} = 1.94(14 \text{ TeV}/1.96 \text{ TeV})^{0.16} = 2.66$  GeV

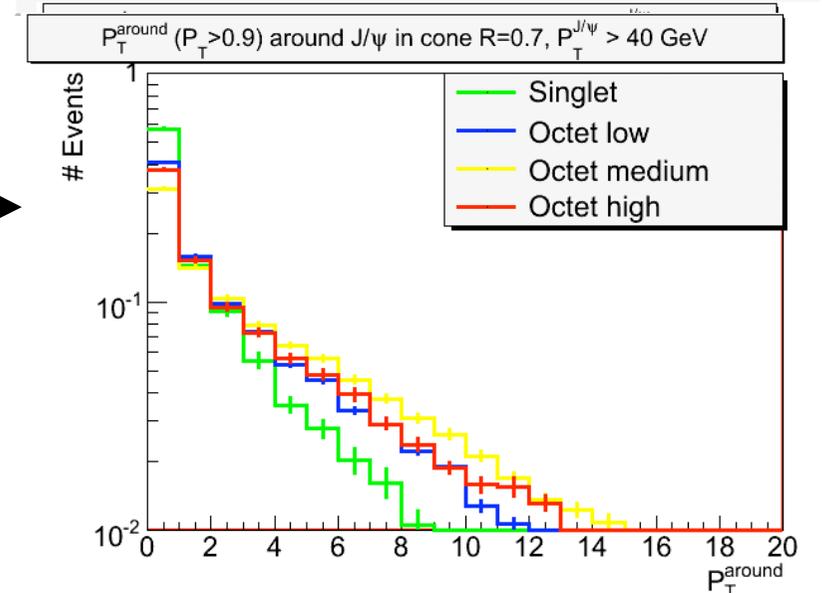

# Activity around J/psi

- Shower activity of 4 models is different (see slide 7) → natural observable:  $N_{ch}$  charged particles ( $P_T > 0.9$ , except  $\mu$ 's) around J/psi in cone with  $R=0.7$

- Scalar sum of  $P_T$  of charged particles around J/psi in cone with  $R=0.7$

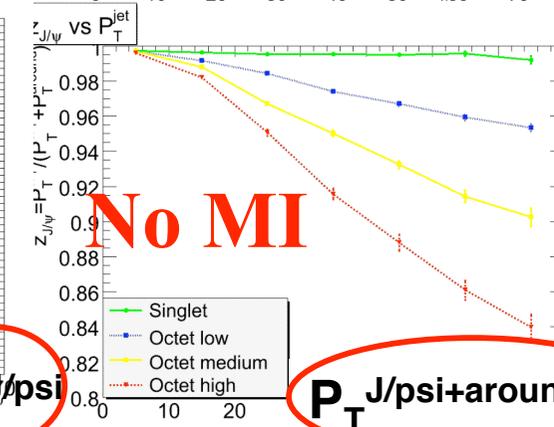

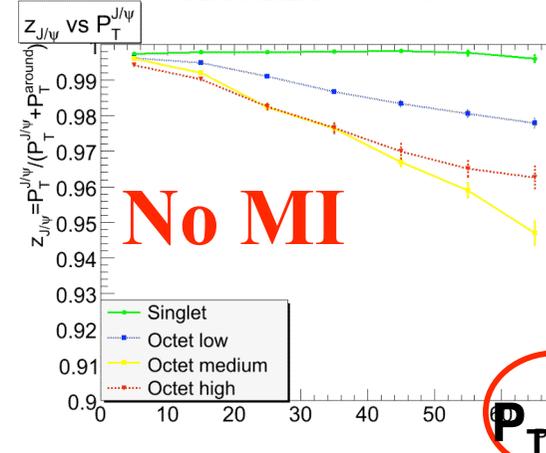

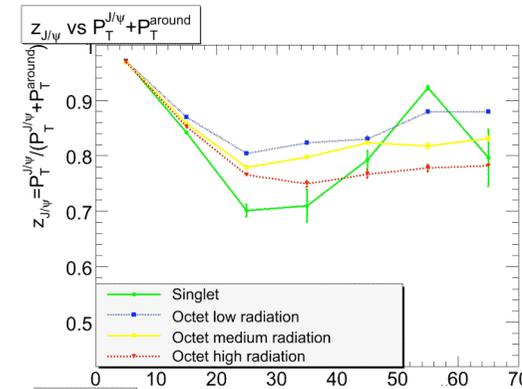

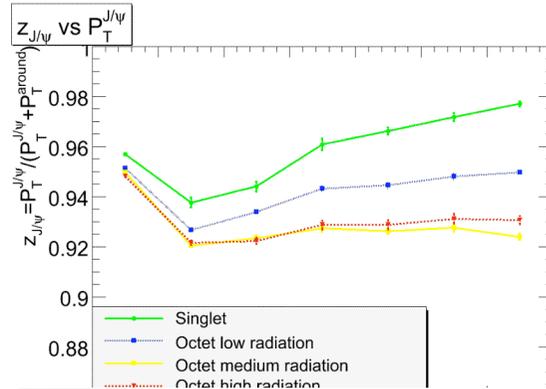

- ✓ The particles around the J/psi are generally low energetic!
- ✓ The differences are at high  $P_T$ (J/psi)

$$z = \frac{P_T^{J/\psi \text{ itself}}}{P_T^{\text{jet}}}$$

# Possible observable: $z_{J/\psi}$

- Since for 4 models fragmentation function is different, try  $z_{J/\psi} \sim$  theoretical fragmentation variable  $z \Rightarrow$  Try  $z_{J/\psi}$  vs  $P_T^{J/\psi}$  and  $z_{J/\psi}$  vs  $P_T^{\text{Jet}}$

- Interesting shape!
- Investigate effect multiple interactions,
- 2M new events

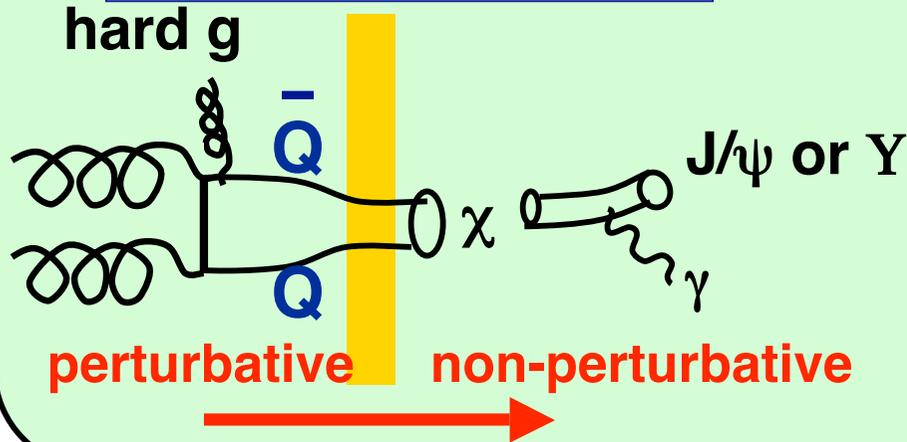

- **Conclusion:** accidental underlying event activity around  $J/\psi$  can be important

- $z_{J/\psi}$  possible observable, but have to understand underlying event

# Parton showers

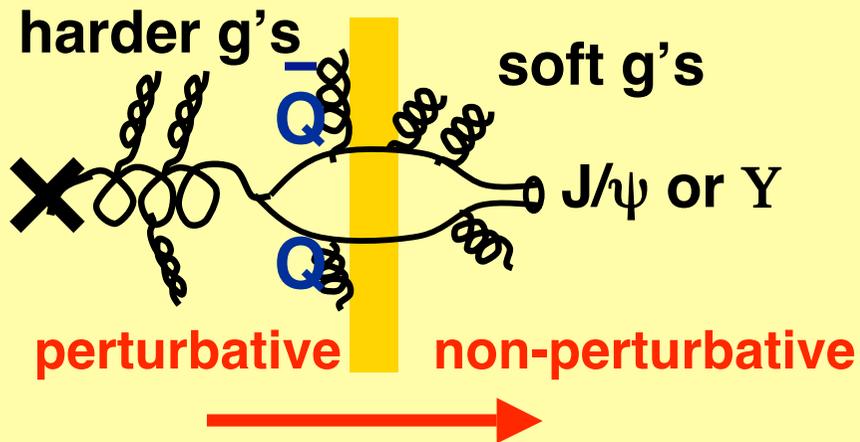

## Singlet production

- Quarkonium produced direct or via  $\chi$
- QQ-state produced in colour singlet in hard interaction
- Color singlet  $\rightarrow$  no g-radiation
- **J/psi produced in isolation!**

**MODEL 1: NO RADIATION**

## Octet production

- Quarkonium produced direct or via  $\chi$
- Physics-wise: shower expected from
  - 1)  $gg \rightarrow ggg \rightarrow gggg \dots$
  - 2)  $g \rightarrow QQ^{(8)}$
  - 3)  $QQ^{(8)} \rightarrow J/\psi$  or  $Y$
- Technically: cc-octet in hard interaction
- Switches MSTP(148), MSTP(149)
- **J/psi produced in shower!**

**MODEL 2: LOW RADIATION**

**MODEL 3: MEDIUM RADIATION**

**MODEL 4: HIGH RADIATION**
